Hedera · The Graph

STATUS

100% testnet

nothing mocked

MITHRA

Two agents that never met, one job neither can lie about.

The work stays private. The proof that it was **the work you ordered** goes on chain.

SOLVED ALREADY

payment
private execution
reputation

MISSING

anything joining them

You can pay an agent and get an answer. Nothing proves it answered *your* question.

Not with your data, not to your brief. Today two strangers need an NDA or a platform in the middle – someone who sees everything and vouches for both sides.

Payment, private execution and reputation are each solved for agents. Nothing connects them.

REJECTION CODES

MatchFalse

BadEnclaveSig

BadClientSig

Expired

ELAPSED

~13 s end to end

One signed commitment, carried from the payment through the enclave to the chain.

JobRejected · MatchFalse

payment not settled – the job was not verified

Make the seller answer a different job and the contract refuses it,
on chain, in front of you. **He did the work and gets nothing.**
Intent-bound verification.

Catches task substitution and input tampering – not prompt injection, and we do not say otherwise.

MESSAGING

ECIES · eth-crypto

PAYMENT

ERC-5564 stealth
on the Base run

WORK

0G Sealed Inference

TESTED

captured traffic scanned
for the plaintext – 0
hits, plain and hex

Three confidential surfaces, one flow, one commitment tying them.

WHAT WAS SAID

The brief and the data are encrypted to the recipient's key. The seller's own server holds ciphertext and cannot read it – the key lives in the enclave.

WHO WAS PAID

On the Base run the payout lands on a fresh stealth address, derived per job. It does not name the seller, and two of his jobs cannot be linked by their payouts.

WHAT WAS DONE

The model runs inside a TEE, so the infrastructure carrying the work cannot see it either.

Each exists on its own elsewhere, and confidential agent payments are not ours to claim first. What does not exist is all three in one job, tied by a single signed commitment – the only reason a chain can rule on work it never sees.

FEE PAYER
0.0.7162784

The proof is the stage that is missing.

- AUTHORISED x402 through the blocky402 facilitator. The buyer authorises – the money stays hers.
- THEN PAID The seller does the work and submits the authorisation only after the contract emits **JobVerified**.
- ON THE TOPIC An honest run ends ... **OUTPUT_COMMIT** → **SETTLED**. A fraud run stops at **OUTPUT_COMMIT**. The missing stage is the whole argument.

Every stage is a commitment, never content – the brief never touches Hedera. This rail buys autonomy, not privacy; the stealth recipient is on the Base run.

WHY

a judge who catches one
overclaim stops
believing the other nine

ALSO NOT

solves prompt injection
first confidential
agent payments
private on Hedera
two TEEs

What we do not claim.

We did not build the TEE.

0G did. We bind it to the client's intent.

Match runs in unattested code.

No TDX host was available, so the client can check it and a stranger cannot. Closing that is next.

Reputation is not Sybil-proof.

Faking it costs real inference and gas, and every client sits in the public index. Paid and visible, not impossible.

The 0G signature covers a fingerprint,

not the answer's text. Same guarantee against tampering, accurate wording.

One write-up per track in the repo, each pointing at the file, the address or the gate you can run yourself.

THE GRAPH

the read layer

HEDERA

the timeline

Four networks. None of them duplicates another.

Drop one and something stops being checkable. Everything you saw is testnet, and every hash on this deck opens on a public explorer without asking us for anything.

Two strangers, one job, no platform in the middle – and the payment moves only after the proof does.
